

# RNA-seq differential expression analysis

SciLifeLab RNA-seq workshop

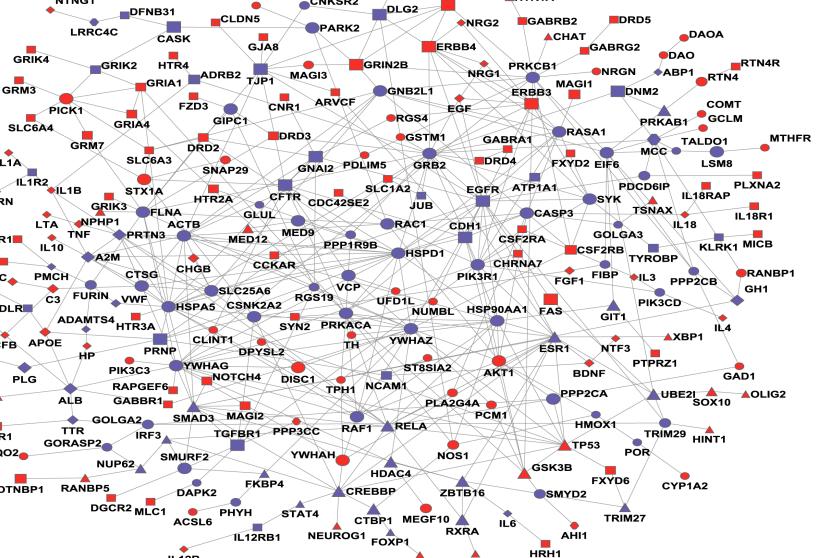

October 26, 2016

Mikael Huss, SciLifeLab / Stockholm University, Sweden

# Differential expression analysis

The identification of genes (or other types of genomic features, such as transcripts or exons) that are expressed in significantly different quantities in distinct groups of samples, be it biological conditions (drug-treated vs. controls), diseased vs. healthy individuals, different tissues, different stages of development, or something else.

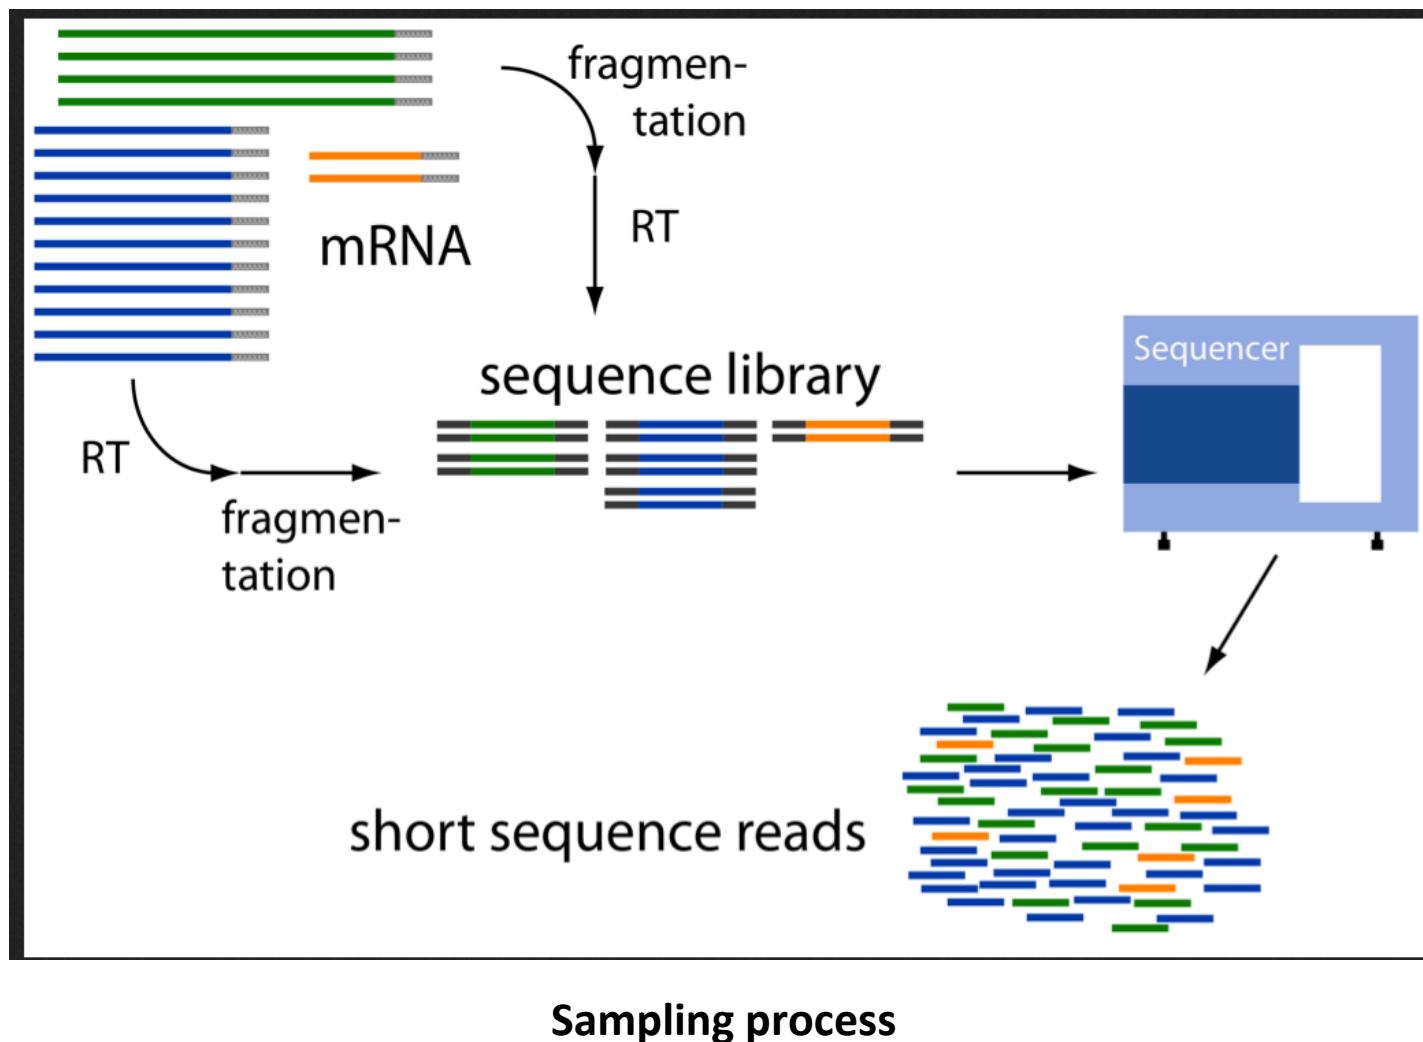

Typically **univariate** analysis (one gene at a time) – even though we know that genes are not independent

# Some statistical aspects

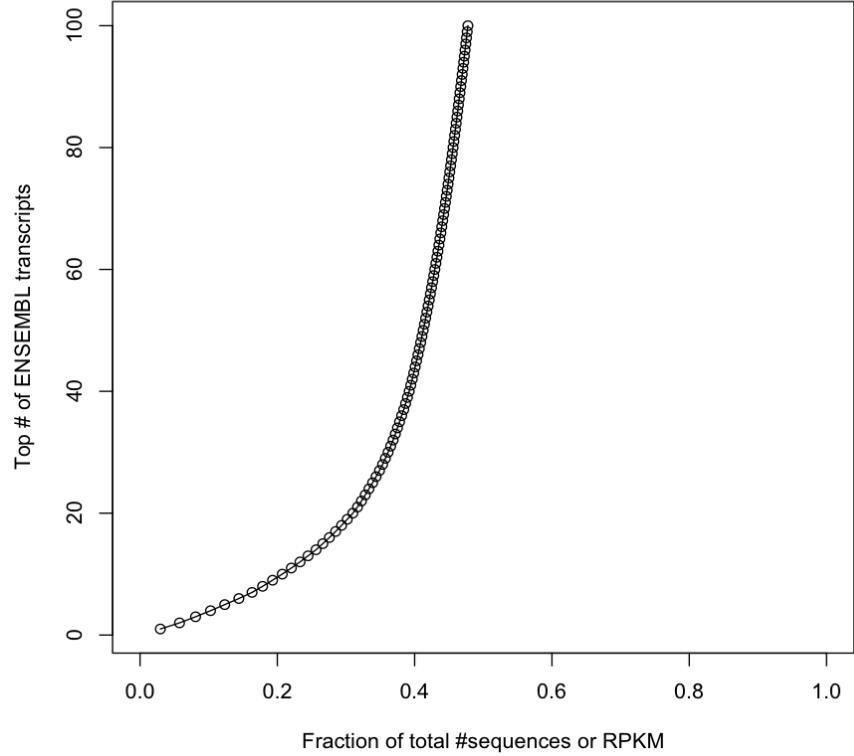

- Properties of RNA-seq data
- Replicates

# How are RNA-seq data generated?

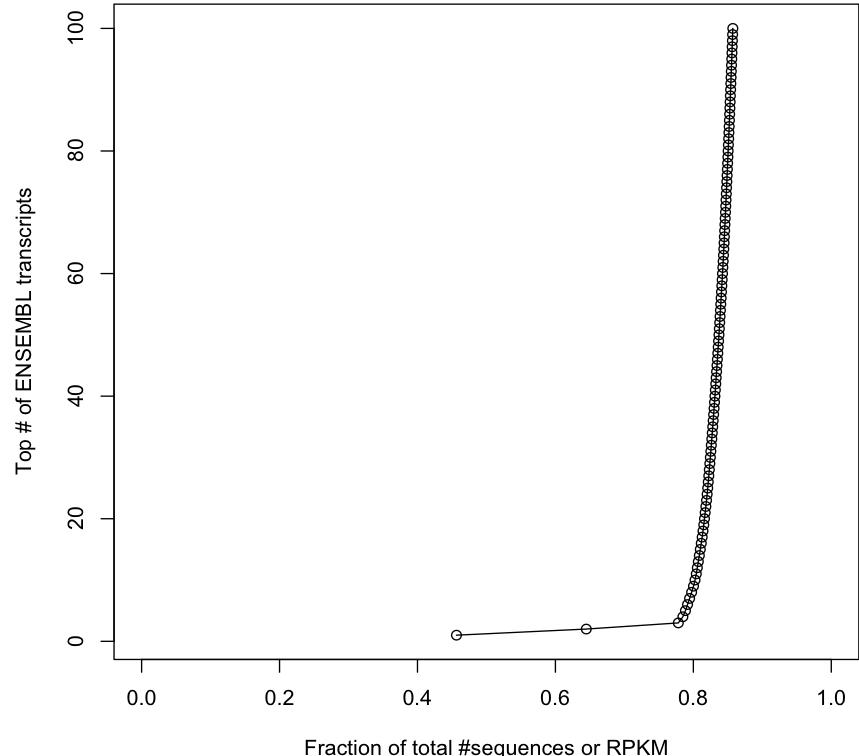

# "Transcriptional real estate"

Heart

Blood

# Count-based statistics

People often use discrete distributions (Poisson, negative binomial etc.) rather than continuous (e.g. normal) distributions for modeling RNA-seq data.

This is natural when you consider the way data are generated.

Thus, many DE analysis tools demand tables of integer read counts as input, rather than RPKM/FPKM/TPM.

# Count nature of RNA-seq data

Programs like edgeR and DESeq2 want to make use of the count nature of RNA-seq data to increase statistical power. The reasoning goes something like this:

(simplified toy example!)

Scenario 1: A 30000-bp transcript has 1000 counts in sample A and 700 counts in sample B.

Scenario 2: A 300-bp transcript has 10 counts in sample A and 7 counts in sample B.

Assume that the sequencing depths are the same in both samples and both scenarios. Then **the RPKM is the same** in sample A in both scenarios, and in sample B in both scenarios.

In scenario A, we can be more confident that there is a true difference in the expression level than in scenario B (although we would want replicates of course!) by analogy to a coin flip – 600 heads out of 1000 trials gives much more confidence that a coin is biased than 6 heads out of 10 trials

# Technical vs biological replicates

## Technical replicates:

- Assess variability of measurement technique
- Typically low for bulk RNA-seq (not necessarily single-cell RNA-seq)
- Poisson distribution can model variability between RNA-seq technical replicates rather well

## Biological replicates:

- Assess variability between individuals / “normal” biological variation
- Necessary for drawing conclusions about biology
- Variability across RNA-seq biological replicates not well modelled by Poisson – usually negative binomial (“overdispersed Poisson”) is used

# Replicates and differential expression

Intuitively, the variation **between** the groups that you want to compare should be large compared to the variation **within** each group to be able to say that we have differential expression.

The more biological replicates, the better you can estimate the variation. But how many replicates are needed?

*Depends:*

Homogeneous cell lines, inbred mice etc: maybe 3 samples / group enough.

Clinical case-control studies on patients: can need a dozen, hundreds or thousands, depending on the specifics ....

# How many biological replicates are needed in an RNA-seq experiment and which differential expression tool should you use?

RNA 22:1–13, 2016

NICHOLAS J. SCHURCH,<sup>1,6</sup> PIETÁ SCHOFIELD,<sup>1,2,6</sup> MAREK GIERLIŃSKI,<sup>1,2,6</sup> CHRISTIAN COLE,<sup>1,6</sup>  
ALEXANDER SHERSTNEV,<sup>1,6</sup> VIJENDER SINGH,<sup>2</sup> NICOLA WROBEL,<sup>3</sup> KARIM GHARBI,<sup>3</sup>  
GORDON G. SIMPSON,<sup>4</sup> TOM OWEN-HUGHES,<sup>2</sup> MARK BLAXTER,<sup>3</sup> and GEOFFREY J. BARTON<sup>1,2,5</sup>

48 wild-type and 48 mutant (snf2 deletion) biological replicates in yeast  
(well studied, relatively small genome, few multi-exonic genes => should be a relatively  
“simple” case)

Recommendation:

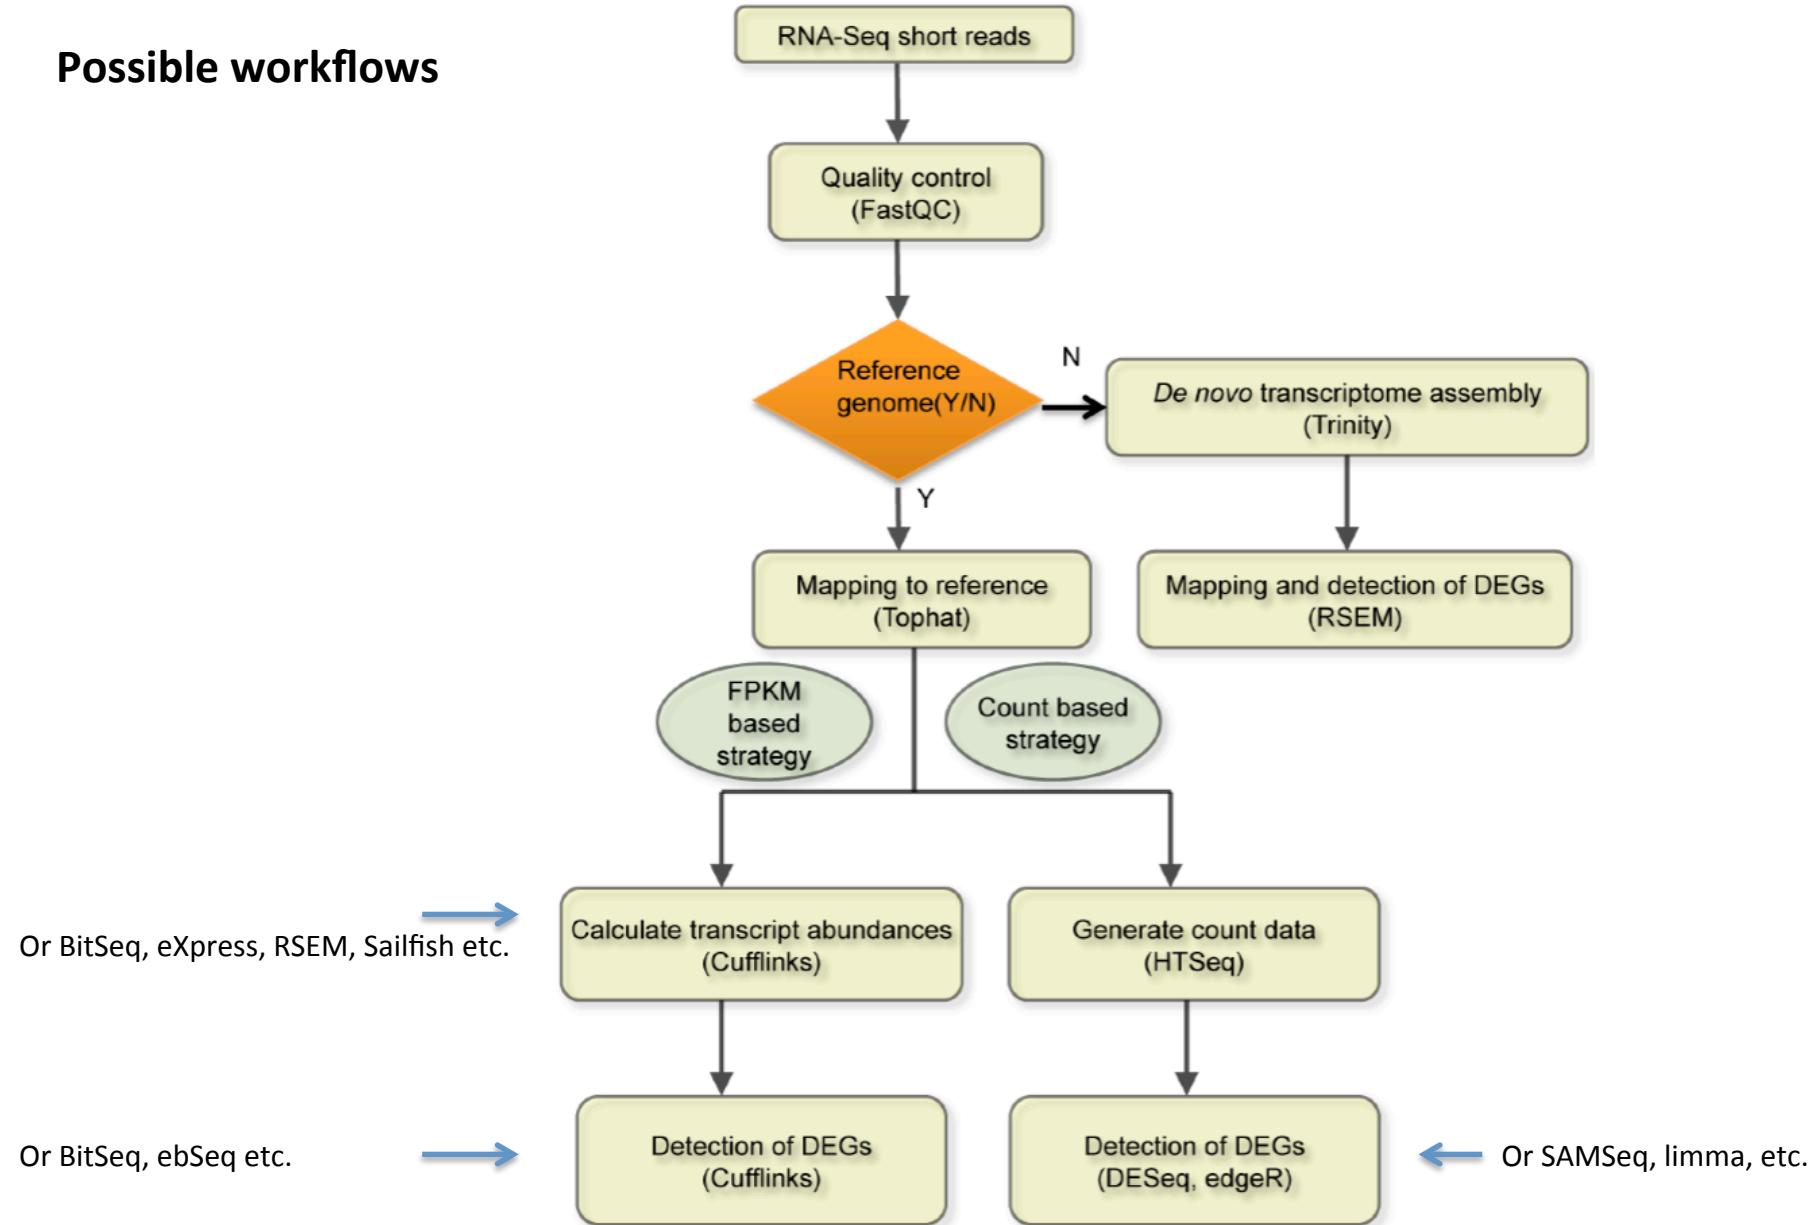

At least six replicates per condition for all experiments.

At least 12 replicates per condition for experiments where  
identifying the majority of all DE genes is important.

# Different software packages and choices

- Mapping vs pseudo-alignment
- Parametric vs non-parametric
- Isoform-level vs gene-level
- Complex vs simple comparisons

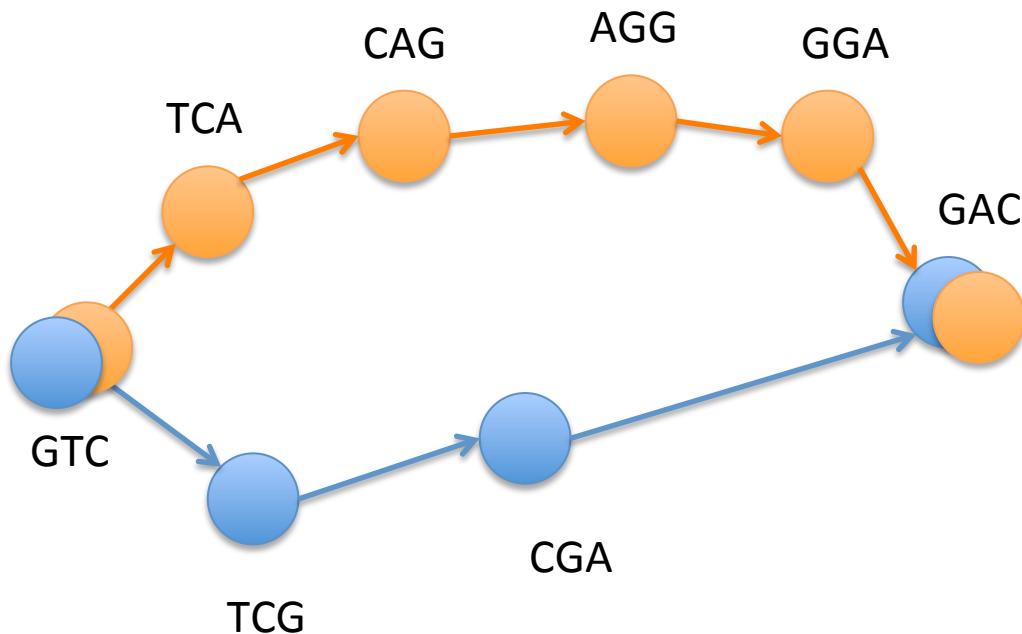

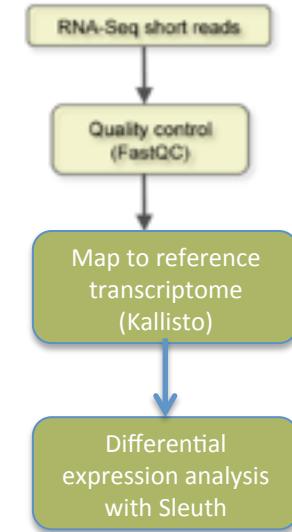

# Possible workflows

## Alternative - Kallisto/Sleuth “pipeline”:

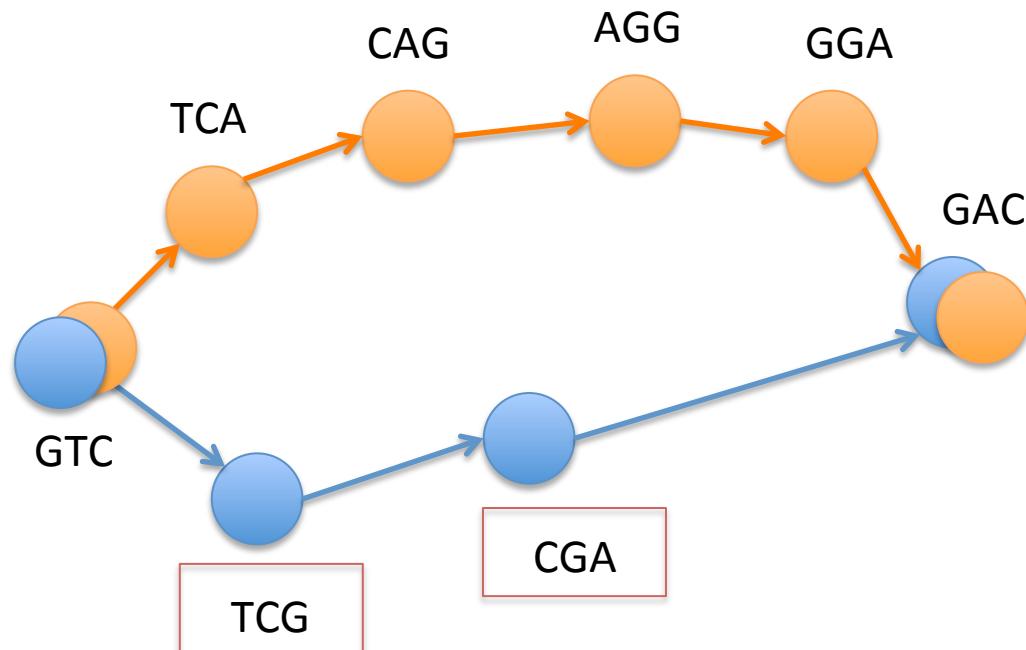

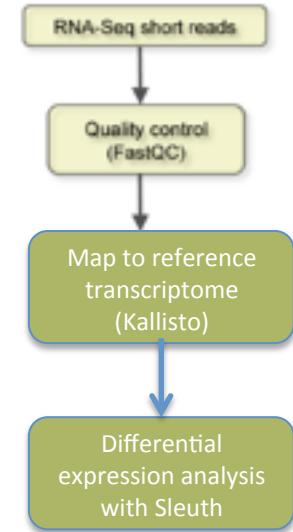

Pseudo-alignment + transcript-centric quantification and DE analysis

- Build an index by chopping ref transcriptomes into k-mers and putting them into “colored” graphs

# Kallisto/Sleuth “pipeline”:

Pseudo-alignment + transcript-centric quantification and DE analysis

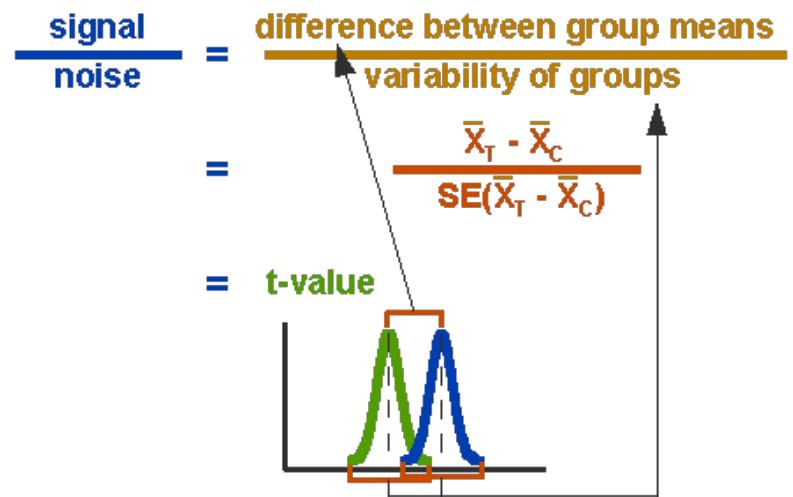

When a new read is observed, chop it into k-mers and see what it is *compatible* with. E.g observe TCGA:

TCGA  
TCGA

# Differential expression analysis?

Couldn't we just use a Student's t test for each gene?

Problems with this approach:

- May have **few replicates**
- **Multiple testing** issues
- Distribution is **not normal**

[http://www.socialresearchmethods.net/kb/stat\\_t.php](http://www.socialresearchmethods.net/kb/stat_t.php)

# Dealing with the “t test issues”

**Variance estimation issue:** edgeR, DESeq2 and limma (in slightly different ways) “borrow” information across genes to get a better variance estimate. One says that the estimates “shrink” from gene-specific estimates towards a common mean value.

# Dealing with the “t test issues”

*Variance estimation issue:* edgeR, DESeq2 and limma (in slightly different ways) “borrow” information across genes to get a better variance estimate. One says that the estimates “shrink” from gene-specific estimates towards a common mean value.

*Multiple testing issue:* All of these packages report q values or some other type of false discovery rate corrected p values. For SAMseq based on resampling, for others usually Benjamini-Hochberg corrected p values.

# Dealing with the “t test issues”

*Variance estimation issue:* edgeR, DESeq2 and limma (in slightly different ways) “borrow” information across genes to get a better variance estimate. One says that the estimates “shrink” from gene-specific estimates towards a common mean value.

*Multiple testing issue:* All of these packages report q values or some other type of false discovery rate corrected p values. For SAMseq based on resampling, for others usually Benjamini-Hochberg corrected p values.

*Distributional issue:* Solved by variance stabilizing transform in limma – voom() function

edgeR and DESeq model the count data using a *negative binomial distribution* and use their own modified statistical tests based on that.

TABLE 8.1 List of (some) Software Tools for Differential Expression Analysis

Software Tool	Type of Software	Analysis Approach	Comment
DESeq	R/Bioconductor package	Count-based (negative binomial)	Considered conservative (low false-positive rate)
edgeR	R/Bioconductor package	Count-based (negative binomial)	Similar to DESeq in philosophy
tweeDESeq	R/Bioconductor package	Count-based (Tweedie distribution family)	More general than DESeq/edgeR, but new and not widely tested
Limma	R/Bioconductor package	Linear models on continuous data	Originally developed for microarray analysis, very thoroughly tested. Need to preprocess counts to continuous values
SAMSeq (samr)	R package	Nonparametric test	Adapted from the SAM microarray DE analysis approach. Works better with more replicates
NOISeq	R/Bioconductor package	Nonparametric test	
CuffDiff	Linux command line tool	Isoform deconvolution + count-based tests	Can give differentially expressed isoforms as well as genes (also differential usage of TSS, splice sites)
BitSeq	Linux command line tool and R package	Isoform deconvolution in a Bayesian framework	Can give differentially expressed isoforms. Also calculates (gene and isoform) expression estimates
ebSeq	R/BioConductor package	Isoform deconvolution in a Bayesian framework	Can give differentially expressed isoforms. Can be used in a pipeline preceded by RSEM expression estimation

# Parametric vs. non-parametric methods

It would be nice to not have to assume anything about the expression value distributions but only use rank-order statistics. -> methods like SAM (Significance Analysis of Microarrays) or SAM-seq (equivalent for RNA-seq data)

However, it is (typically) harder to show statistical significance with non-parametric methods with few replicates.

According to Simon Anders (creator of DESeq) non-parametric methods are definitely better with 12 replicates and maybe already at five

<http://seqanswers.com/forums/showpost.php?p=74264&postcount=3>

... but ...

# But: Revisiting the 48-replicate benchmark paper

**TABLE 1.** RNA-seq differential gene expression tools and statistical tests

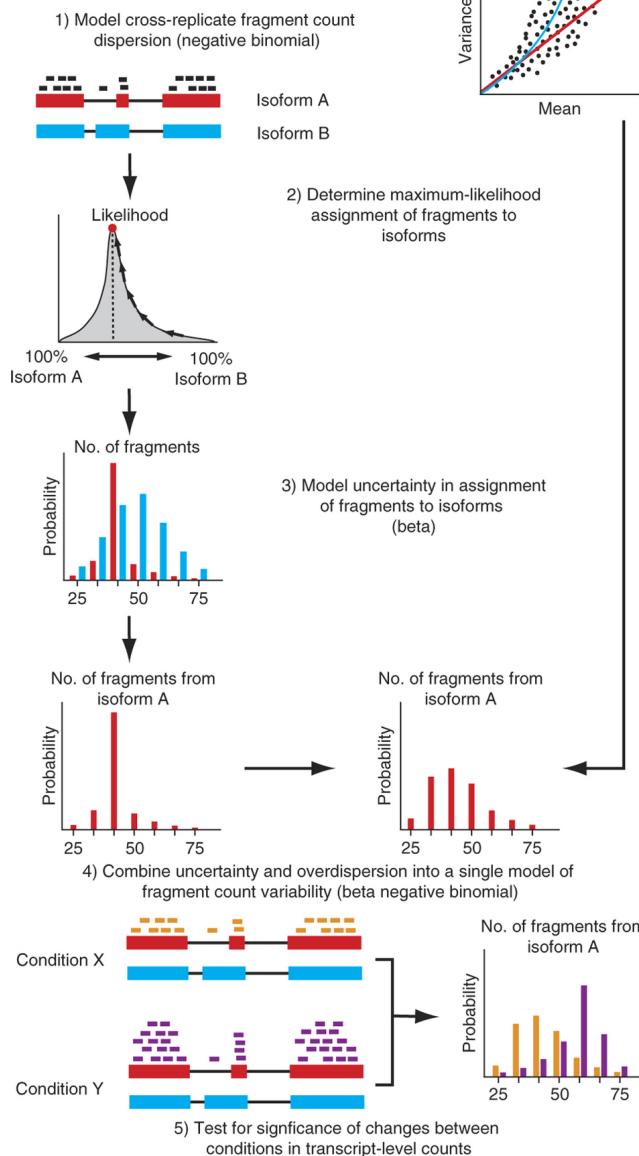

Name	Assumed distribution	Normalization	Description
<i>t</i> -test	Normal	DEseq <sup>a</sup>	Two-sample <i>t</i> -test for equal variances
log <i>t</i> -test	Log-normal	DEseq <sup>a</sup>	Log-ratio <i>t</i> -test
Mann-Whitney	None	DEseq <sup>a</sup>	Mann-Whitney test
Permutation	None	DEseq <sup>a</sup>	Permutation test
Bootstrap	Normal	DEseq <sup>a</sup>	Bootstrap test
<i>baySeq</i> <sup>c</sup>	Negative binomial	Internal	Empirical Bayesian estimate of posterior likelihood
Cuffdiff	Negative binomial	Internal	Unknown
<i>DEGseq</i> <sup>c</sup>	Binomial	None	Random sampling model using Fisher's exact test and the likelihood ratio test
<i>DESeq</i> <sup>c</sup>	Negative binomial	DEseq <sup>a</sup>	Shrinkage variance
<i>DESeq2</i> <sup>c</sup>	Negative binomial	DEseq <sup>a</sup>	Shrinkage variance
<i>EBSeq</i> <sup>c</sup>	Negative binomial	DEseq <sup>a</sup> (median)	Empirical Bayesian estimate of posterior likelihood
<i>edgeR</i> <sup>c</sup>	Negative binomial	TMM <sup>b</sup>	Empirical Bayes estimation and either an exact test analogous to Fisher's exact test but adapted to over-dispersed data or a generalized linear model
<i>Limma</i> <sup>c</sup>	Log-normal	TMM <sup>b</sup>	Generalized linear model
<i>NOISEq</i> <sup>c</sup>	None	RPKM	Nonparametric test based on signal-to-noise ratio
<i>PoissonSeq</i> <sup>c</sup>	Poisson log-linear model	Internal	Score statistic
<i>SAMSeq</i> <sup>c</sup>	None	Internal	Mann-Whitney test with Poisson resampling

For experiments with <12 replicates per condition; use *edgeR* (*exact*).

For experiments with >12 replicates per condition; use *DESeq*.

Parametric methods apparently working better ...

# CuffDiff2

Integrates isoform quantification + differential expression analysis.

Also: **BitSeq**

# Sleuth

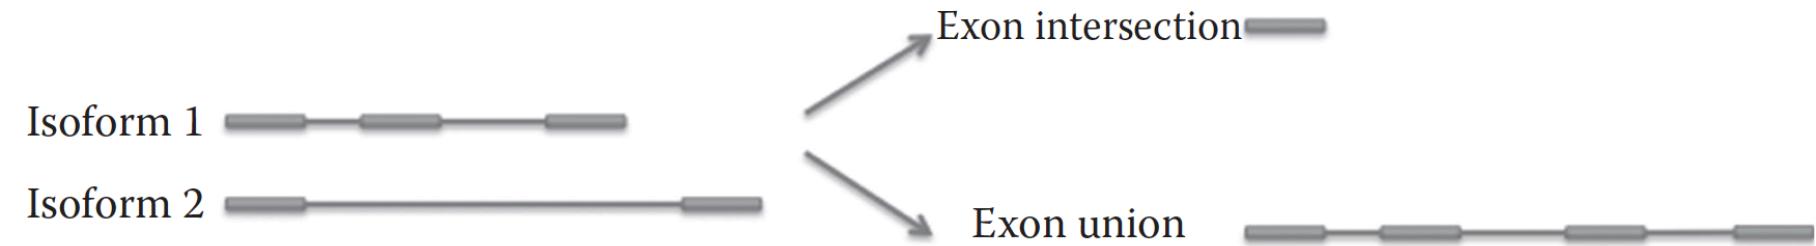

Developed by the same team as CuffDiff, and superior to it according to them. Based on Kallisto.

Transcript-oriented (like CuffDiff)

Includes uncertainty coming from “quantification noise” (like CuffDiff)

Supports modelling multiple experimental factors (unlike CuffDiff)

# Reason to use transcript-level analysis

Condition A	Condition B	Fold change (actual)	Fold change (union)	Fold change (intersection)
 Isoform 1: 12/3L; 4/3L	 Isoform 1: 12/3L; 4/3L	38/30	14/14	7/7
 Isoform 2: 2/2L; 10/2L	 Isoform 2: 2/2L; 10/2L	Condition A: 12/3L + 2/2L = 30/6L Condition B: 4/3L + 10/2L = 38/6L		

# Complex designs

The simplest case is when you just want to compare two groups against each other.

But what if you have several factors that you want to control for?

# Complex designs

The simplest case is when you just want to compare two groups against each other.

But what if you have several factors that you want to control for?

E.g. you have taken tumor samples at two different time points from six patients, cultured the samples and treated them with two different anticancer drugs and a mock control treatment. ->  $2 \times 6 \times 3 = 36$  samples.

# Complex designs

The simplest case is when you just want to compare two groups against each other.

But what if you have several factors that you want to control for?

E.g. you have taken tumor samples at two different time points from six patients, cultured the samples and treated them with two different anticancer drugs and a mock control treatment. ->  $2 \times 6 \times 3 = 36$  samples.

Now you want to assess the differential expression in response to one of the anticancer drugs, drug X. You could just compare all “drug X” samples to all control samples but the inter-subject variability might be larger than the specific drug effect.

# Complex designs

The simplest case is when you just want to compare two groups against each other.

But what if you have several factors that you want to control for?

E.g. you have taken tumor samples at two different time points from six patients, cultured the samples and treated them with two different anticancer drugs and a mock control treatment. ->  $2 \times 6 \times 3 = 36$  samples.

Now you want to assess the differential expression in response to one of the anticancer drugs, drug X. You could just compare all “drug X” samples to all control samples but the inter-subject variability might be larger than the specific drug effect.

→ limma / DESeq / edgeR / Sleuth which can work with factorial designs

(but not e.g CuffDiff2, SAMSeq)

# Limma and factorial designs

limma stands for “linear models for microarray analysis” – but it can be used for RNA-seq after applying voom() to a count matrix

Essentially, the expression of each gene is modeled with a linear relation

## Linear Models

- In general, need to specify:
  - Dependent variable
  - Explanatory variables (experimental design, covariates, etc.)
- More generally:

$$y = X\beta + \epsilon$$

↑      ↑      ↗  
vector of    design    Vector of  
observed    matrix    parameters to  
data                estimate

[http://www.math.ku.dk/~richard/courses/bioconductor2009/handout/19\\_08\\_Wednesday/KU-August2009-LIMMA/PPT-PDF/Robinson-limma-linear-models-ku-2009.6up.pdf](http://www.math.ku.dk/~richard/courses/bioconductor2009/handout/19_08_Wednesday/KU-August2009-LIMMA/PPT-PDF/Robinson-limma-linear-models-ku-2009.6up.pdf)

The design matrix describes all the conditions, e.g treatment, patient, time etc  
 $y = a + b*treatment + c*time + d*patient + e*batch + f$

Baseline/average

Error term/noise

# Which software to choose?

edgeR, DESeq

# Take-away messages from DE tool comparison

- edgeR, DESeq and limma (the latter of which does not use the negative binomial distribution) tend to work well
- CuffDiff2, which should theoretically be “better”, seems to work worse, perhaps due to the increased “statistical burden” from isoform expression estimation. Two studies also report poor performance with >5 replicates
- The HTSeq quantification which is theoretically “wrong” seems to give good results with downstream software
- It is practically always better to sequence more biological replicates than to sequence the same samples deeper

Not considered in these comparisons:

- gains from ability to do complex designs
- isoform-level DE analysis (hard to establish ground truth)
- some packages like BitSeq, Sleuth

# Miscellaneous (if there is time)

- Visualization of DE analysis results
- Normalization and scaling
- Batch normalization
- Mixtures of cell types
- Beyond univariate DE analysis

# Differential expression analysis output

# Normalization/scaling/transformation: different goals

- **R/FPKM:** (Mortazavi et al. 2008)
  - **Correct for:** differences in sequencing depth and transcript length
  - **Aiming to:** compare a gene across samples and diff genes within sample
- **TMM:** (Robinson and Oshlack 2010)
  - **Correct for:** differences in transcript pool composition; extreme outliers
  - **Aiming to:** provide better across-sample comparability
- **TPM:** (Li et al 2010, Wagner et al 2012)
  - **Correct for:** transcript length distribution in RNA pool
  - **Aiming to:** provide better across-sample comparability
- **Limma voom (logCPM):** (Law et al 2013)
  - **Aiming to:** stabilize variance; remove dependence of variance on the mean

## Optimal Scaling of Digital Transcriptomes

Gustavo Glusman , Juan Caballero, Max Robinson, Burak Kutlu, Leroy Hood

Published: Nov 06, 2013 • DOI: 10.1371/journal.pone.0077885

# TMM – Trimmed Mean of M values

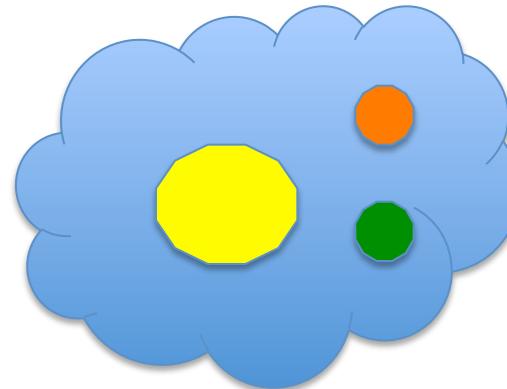

Attempts to correct for differences in RNA *composition* between samples

E.g if certain genes are very highly expressed in one tissue but not another, there will be less “sequencing real estate” left for the less expressed genes in that tissue and RPKM normalization (or similar) will give biased expression values for them compared to the other sample

RNA population 1

RNA population 2

Equal sequencing depth -> orange and red will get lower RPKM in RNA population 1 although the expression levels are actually the same in populations 1 and 2

Robinson and Oshlack Genome Biology 2010, 11:R25, <http://genomebiology.com/2010/11/3/R25>

# Normalization in DE analysis

edgeR, DESeq2 and some others want to keep the (integer) read counts in the DE testing because they

- Use a discrete statistical model
- Want to retain statistical power (see next slide)

... but they **implicitly** normalize (by TMM in edgeR and RLE in DESeq2) as part of the DE analysis.

Programs like SAMSeq and limma are fine with continuous values (like FPKM), the former because it has a **rank based model** and the latter because it cares more about the **mean-variance relationship** being weak. They also apply their own types of normalization as part of the DE testing.

# Batch normalization

Often, putting the experimental batch as a **factor** in the **design matrix** is enough.

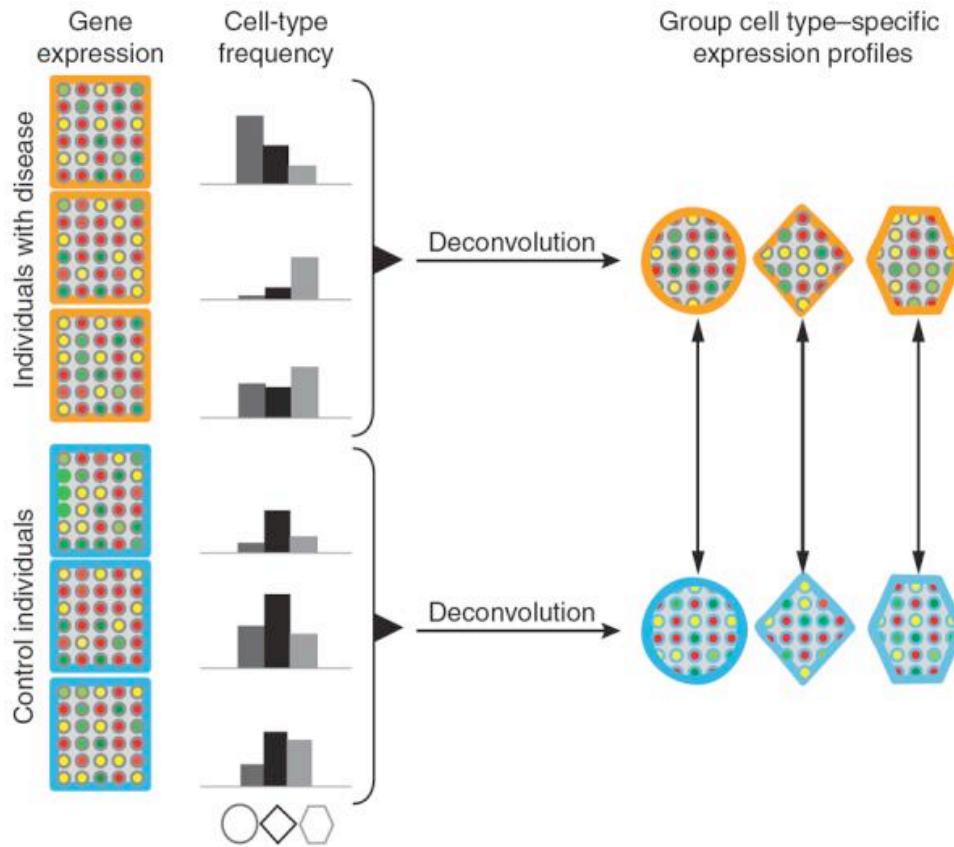

If you wish to explicitly normalize away the batch effects (to get a new, batch-normalized expression matrix with continuous values), you can use a method such as ComBat.

(Designed for microarrays, should use log scale values for RNA-seq)

**COMBAT:**  
**'COMBATTING' BATCH EFFECTS WHEN COMBINING**  
**BATCHES OF GENE EXPRESSION MICROARRAY DATA**

# Beyond univariate differential expression (1)

Multivariate methods such as PCA (unsupervised) or PLS (supervised) can be used to obtain loadings for features (genes/transcripts/...) that contribute to separation of groups

The loading scores can be used as a different kind of measure of which genes are interesting

# Beyond univariate differential expression (2)

Statistical/machine learning approaches:

Can use gene or transcript expression levels as features in a statistical model when trying to predict some class (classification) or continuous variable (regression)

Feature selection methods frequently needed to reduce the number of genes/transcripts used in the model. E.g lasso/elastic net or Boruta (random forest based feature selection).
